Two decades ago, gastroenterologists used endoscopy for the diagnosis of Gastrointestinal (GI) lesions, thereby helping surgeons to localize lesion that necessitated resection and treatment with surgery. Today, the gastroenterology field has advanced beyond the diagnostic era and now, a large number of GI lesions can be treated via endoluminal procedures performed by the gastroenterologist with no need for surgical intervention.

In recent years, the improvement of endoscopic imaging and tools, such as snares, clips and needles which can be delivered through the endoscope channel, have helped to change the field of gastroenterology. This allowed for the development and advancement of Endoscopic Mucosal Resection (EMR) and Endoscopic Submucosal Dissection (ESD). The pioneers of EMR and ESD were from Japan and the first articles describing these techniques were published in the 1990s.¹ ²

Two classification systems are used for describing GI lesions to be considered for EMR and ESD. One system is the Japanese classification³ and the second is the Paris system, which was proposed in 2002.⁴ The Japanese classification was originally developed for early gastric cancer management, but it can be applied to lesions throughout the GI tract. Once lesions are classified, EMR can be performed in different GI locations, including the esophagus, stomach, colon and rectum. When lesions are more complex and beyond the mucosa, ESD can be performed with careful dissection.

Endoscopic ultrasound (EUS) may be useful in deciding whether to perform EMR or ESD. EUS can aid in determining the penetration of the tumor to layers beyond the mucosa when the lesion is localized in proximal parts of the colon. If the lesion cannot be reached by a regular EUS endoscope special high frequency mini-probes may be used through the colono­scope working channel.

Two methods are used in performing EMR. The first method is ‘suck and cut’ and the second method is ‘lift and cut’. Both usually begin with a submucosal injection prior to resection of the lesion the suc and cut method may be used also without submucosal injection especially when being performed in the esophagus. The injection is used to expand the submucosa, separating the deeper muscularis propria from the more superficial mucosa and submucosa layers. Several solutions may be used as the injectate. These include normal saline with or without diluted epinephrine, hypertonic saline, dextrose solution, sodium hyaluronate, fibrinogen combination, glycerol, and fructose solutions all of those may be mixture with methylene blue depend on the preference of the endoscopist.⁵-⁸ Conio, et al. compared the solutions and showed that the disappearing time of normal saline is approximately 3 minutes with or without epinephrine, while the disappearing times of 50% dextrose and 10% glycerol and hyaluronic acid solutions were 4.7, 4.2 and 22 minutes respectively.⁹

After injection, one of the two resection methods can be applied. The ‘suck and cut’
method utilizes a transparent cap on the endoscope and requires suctioning of the lesion into the cap. The lesion is then resected by a snare which exits through the working channel into the transparent cap. A variation of this method is the use of bands instead of an injection solution, and this method is best for the treatment of esophageal lesions. Following injection, the ‘lift and cut’ method involves the use of a grasper to pull the lesion from the muscularis propria. The ‘lift and cut’ method was the first EMR technique, but because of complexity, the ‘suck and cut’ method is now used more widely.

When the lesion is thought to be deeper or wider, if it is a submucosal lesion, or if en bloc resection is preferred, ESD may be used for resection. ESD includes the same inject and lift method as EMR, but instead of using a snare, needle knife is used to resect the lesion through dissection. ESD can be performed in different GI locations such as esophagus, stomach, duodenum, colon and rectum.

Once removal of the lesion is complete, tattooing of the procedure area can be considered in order to assist in surveillance. Use of India ink tattooing is recommended, but careful injection is necessary as India ink ink can result in tissue scarring if injected to the submucosal space. One method to prevent scarring is to first inject normal saline to separate the mucosa and the submucosal layers and then inject the ink.

The long term outcomes of both EMR and ESD have been positive. Merkow, et al. compared the outcomes of patients with early esophageal cancer treated by EMR or surgery. There was a higher 30 day mortality rate in the surgical group and 5 year survival was 77% and 88% in the EMR and surgical groups respectively. EMR for gastric lesions (when the margins of the lesion are clear with no dysplasia) has also had favorable outcomes. The outcomes of colonic EMR for early colon cancer are similar to the results in esophageal and gastric EMR. Bledsoes, et al. reported the results of a meta-analysis of colonic EMR showing that the recurrence rate was 15% and that piecemeal resection had a higher recurrence rate as compared to en bloc resection (20% versus 3% respectively). Ikematsu, et al. reported long term outcomes after resection of submucosal invasive colorectal cancer by ESD or surgery. In patients with low risk lesions (lesion entirely resected, well to moderately differentiated adenocarcinoma, no vascular invasion and submucosal invasion <1 mm), there were recurrence rates of 0% and 6% for rectal and colonic lesions, while in patients with high risk lesions, the recurrence rates were 1.4% and 16% for rectal and colonic lesions respectively.

Both EMR and ESD can lead to adverse events and in order to lower complication rates the procedures should be performed by experienced endoscopists. Adverse events, including perforations, strictures, and immediate or late bleeding during esophageal EMR were reported to be present in 0% to 13% of cases. Gastric EMR adverse events have been reported to range from 1% to 5%. In colonic EMR, bleeding events may occur in as many as 24% of cases. Colonic ESD may be complicated by perforation in up to 10% of cases as reported by Tamgai, et al. but in most cases the perforation may be treated endoscopically without the need for surgical intervention.

In conclusion, EMR and ESD will continue to be performed worldwide, likely with increased frequency, during the next several years. Nonetheless, in order to avoid and reduce complications, it is recommended that EMR and ESD be performed at high volume centers and by experienced endoscopists.
