ABSTRACT

Introduction: Mucoceles are cystic masses developing after obstruction of the sinus ostium. The symptoms are not specific. Computed Tomography scan (CT scan) and Magnetic Resonance Imaging (MRI) confirm the diagnosis.

Objectives: We herein review the radiologic characteristics of mucoceles in CT scan and MRI.

Materials and Methods: We report a retrospective study of 43 patients diagnosed with paranasal sinuses mucoceles. CT scans were performed for all patients, but MRI was carried out only in selected cases.

Results: Our study was constituted of 27 males and 16 females with a mean age of 47 years. The CT scan appearance of mucoceles were in all cases as a well circumscribed expansile sinus mass with an effect on the neighbor bone structure. This mass was hypodense in 26 cases, isodense in 14 cases and hyperdense in 3 patients. The paranasal sinuses most frequently affected in our series were the fronto-ethmoidal sinuses. The most affected bone eroded was the lamina papiracea. Intracranial extension was seen in four cases. CT scan allowed to predict the cause of mucoceles in some cases and to provide information about anatomic variants. MRI was realized for 15 patients in addition to the CT scan. It allowed to study the extension of mucoceles to the neighboring organs especially orbital and endocranial ones.

Conclusion: The presentations of mucoceles on imaging are quite variable. CT scan provides precious information about the location, bone erosion and extension of the mucoceles. MRI is indicated in some cases especially in cases of orbital or cranial extension.

KEYWORDS: Mucoceles; Paranasal sinuses; Computed Tomography scan (CT scan); Magnetic Resonance Imaging (MRI).

ABBREVIATIONS: CT scan: Computed Tomography scan; MRI: Magnetic Resonance Imaging.

INTRODUCTION

Mucoceles are benign, slow-growing paranasal sinus lesions that develop after obstructions of the sinus ostium.1 Symptoms are variable. The diagnosis is based on imaging. CT scan of the sinuses is the method of the choice. MRI is indicated in some cases and provides much information of mucocele extensions to adjacent compartments.2

The purpose of this study was to review the role of pre-operative imaging and to illustrate the main characteristics imaging findings of paranasal sinuses mucoceles.

MATERIALS AND METHODS

We conducted a retrospective review of the charts of 43 patients diagnosed with paranasal sinus mucoceles who were admitted to our Department of Otolaryngology, between January 1990 and December 2012.

Review of the patients’ medical records including out-patient clinical records and reports of imaging were performed.
CT scans of the head were performed for all patients. Axial, sagittal, coronal and contrast CT scan with 3 mm slice thickness were reviewed in all cases.

MRI was carried out only in selected cases for the evaluation of the extension of sinonasal mucoceles. MRI findings on coronal and axial views in T1, T2 weighted and contrast enhanced images were studied.

RESULTS

Clinical Features

Our study was constituted of 27 males and 16 females (sex ratio=1.68) with a mean age of 47 years (from 14 to 77 years).

Rhinosinusitis past history was present in six patients, a facial traumatism in seven patient and eleven patients have undergone prior sinus surgery.

The most commonly reported symptoms were ophthalmologic one (n=24, 56%), including proptosis (n=16), chronic lacrimation (n=7), diplopia (n=3), visual acuity reduced (n=2) and ptosis (n=1).

Headache was present in twenty three patients. Rhinologic symptoms were reported in 20 patients and were dominated by chronic discharge (17 cases).

On examination, we noted a face swelling in 17 cases, a proptosis in 16 patients and ophtalmoplegia in two cases.

Endoscopic nasal examination revealed an obstructive deviation of nasal septum in 10 cases, a filling of middle meatus in six patients and adhesions between the middle turbinate and the nasal septum in three cases.

Radiologic Findings

CT scan: The CT scan appearance of mucoceles were in all cases as a well circumscribed expansile sinus mass with an effect on the neighbor bone structure. This mass was hypodense in 26 cases, isodense in 14 cases and hyperdense in 3 patients. After injection of contrast agents, we saw a poor enhancement in three cases and a peripherally enhanced image in all others cases.

The paranasal sinuses most frequently affected in our series were the fronto-ethmoidal sinuses (Figure 1). Mucoceles involved both the frontal and ethmoidal sinus in fourteen cases, ten mucoceles were located in the ethmoid sinus, and five were located in the frontal sinus (Figures 2, 3 and 4).

Bone erosion was noted (Figures 5 and 6). The most affected was the lamina papiracea which was eroded in 27 cases (Table 1).

Intracranial extension was seen in four cases and was...
consequently to a frontal mucocele in one case, fronto-ethmoidal mucocele in two cases, sphenoid-ethmoidal mucocele in one other case (Figure 7).

Extension into the orbit was observed in 27 cases and concerned predominately the medial wall of the orbit. Optic nerve was repulsed in two cases of fronto-ethmoidal mucoceles and one case of fronto-ethmoidal-maxillary mucocele. It was compressed in others three cases of: Ethmoidal, Sphenoidal and Spheno-ethmoidal mucoceles. We noted one case of atrophic optic nerve in a sphenoidal mucocele (Figures 8, 9 and 10).

CT scan allowed to note a proptosis in 17 cases (grade 2 in 16 patients and grade 3 in one patient with a fronto-ethmoidal mucocele associated with an important orbital extension) Others lesions were observed some predicted of the cause of mucoceles:

*Adhesions between the middle turbinate and lateral nasal wall were observed in three patients who had prior sinus surgery and were seen respectively in an ethmoidal, sphenoidal and fronto-ethmoidal maxillary mucoceles.

*Calcifications of the frontal recess in one patient having a frontal mucocele and history of craniofacial traumatism.

*Sinus retention were noted in three cases of maxillary mucoce-
le, fronto-ethmoidal and fronto-ethmoido-maxillary mucocele.

*Concha bullosa was present in four patients presenting: Ethmoidal mucocele, Fronto-ethmoidal mucocele, Maxillary mucocele and Nasal cavity mucocele. (Figure 11)

*Hypoplastic frontal sinuses was noted in one case of ethmoidal mucocele.

*Agenesis of the frontal sinus in one case of ethmoidal mucocele. (Figure 12)

*Presence of a frontal cell (kuhn’s cell) in a frontal mucocele. (Figure 13)

*Paradoxical middle turbinate in one patient having a fronto-ethmoidal mucocele.

*Septum deviation was observed in 17 patients and were obstructive in 10 cases.

CT scan provided also information about anatomic variants. We noted:

*Procidence of the canal of the carotid artery in four cases. It was bilateral in three cases (frontal, maxillary and sphenoid mucocele) and unilateral in one case of fronto-ethmoidal mucocele associated with the presence of a sphenoid sinus septa attached to the artery canal.

*Procidence of the optic nerve canal in one case of a frontal mucocele.

*Asymmetry in the height of the ethmoid roof in two cases of a fronto-ethmoidal mucoceles.

**MRI:** MRI was realized for 15 patients in addition to the CT scan. It was indicated in four cases of sphenoid mucoceles (Figure 14) and in 11 cases presenting orbital or endocranial extension on CT scan.

Mucoceles appeared as a homogenous round mass who was in:

- Hypointense signal on T1-weighted images, hyperintense signal on T2-weighted images in nine cases.

- Hyperintense signal on T1-weighted and T2-weighted images in two cases.

- Hypointense signal on T1-weighted images, isointense signal on T2-weighted images in two cases.
- Isointense signal on T1-weighted images, hyperintense signal on T2-weighted images in one case.

- Isointense signal on T1-weighted and T2-weighted images in one case.

In all cases, we have noted no enhancement after injection of gadolinium.

MRI allowed to study the extension of mucoceles to the neighboring organs especially orbital and endocranial ones. We observed that:

- The orbite contents was repulsed in two cases of fronto-ethmoido-maxillary mucoceles and one case of fronto-ethmoidal mucocele. (Figure 15)

- Optic nerve was pushed in three patients who had respectively sphenoid mucocele, spheno-ethmoidal mucocele, fronto-ethmoido-maxillary mucocele.

It was stretched in one case of fronto-ethmoidal mucocele with important orbital extension.

- Endocranial extension was noted in three cases: Sphenoid mucocele, fronto-ethmoidal mucocele and fronto-ethmoido-maxillary mucocele. (Figure 16)

**DISCUSSION**

Paranasal sinus mucoceles are cystic masses filled with mucous and lined by respiratory epithelium which are capable of expansion by bone resorption and new bone formation.¹

They occur principally in the third or fourth decades of life with a male predilection.²

Mucoceles result from the blockage of the sinus drainage secondary to inflammation, trauma, anatomical aberrations, tumors. chronic rhinosinusitis, allergic disease and craniofacial disease are the most common cause of mucocele formation.²³

Symptoms depend on the location of the mucocele and may vary from rhinological, neurologic, or ophthalmologic ones.¹³

CT scan is considered to be the complementary method of choice in the investigation of mucoceles. It allows to evoke the diagnosis of the mucocele and determine its location, to study the neighboring structure (bone erosion, extension), to presume an aetiology of the sinus ostium obstruction and to research the anatomic variants of the sinuses.³⁴

Mucocele appears on CT as a homogenous well circumscribed expansible cyst involving one or much sinuses and
may expand to neighboring structure. they may appear either hypo- or hyperdense. This variable densities depend on their protein content and possible infection. Mucoceles do not show contrast enhancement centrally but a thin peripheral enhancement, can be seen and is suggestive of encapsulation.

The differential diagnosis for mucocele is made with inflammatory, congenital cystic and neoplastic lesions of skull base, facial sinuses and nasopharynx. Mucocele location depends on anatomic conditions that favourise its formation. The frontal sinus is most commonly affected followed by the ethmoid sinuses, mucoceles occur in these locations in 70 to 90%. Sphenoid mucoceles are rare. The maxillary antrum is a relatively unfrequent site for mucocele formation, accounting for 10 percent or less of mucoceles.

In our study, mucoceles were seen frequently in fronto-ethmoidal sinus followed by ethmoidal location then frontal sinus.

The neighboring bone structure is remodeled with areas of thickening and erosion. In some areas of greater fragility, we may observe herniation into adjacent structures such as the orbit and the endocrine.

CT scan provides also information about existence of factors favourising mucocele formation as: Osteoma, Fibrous dysplasia, Facial traumatism, Sinonasal polyposis. It can visualizes anatomic abnormalities that may cause a blockage of sinus drainage. For our patients, CT scan has allowed to evoke the cause of mucoceles in some cases as adhesions, concha bullosa, septum deviation, paradoxical middle turbinate.

Furthermore, this exam is essentially to define anatomic variants prior to surgery.

MRI is an excellent exam in mucoceles. It allows to differentiate and to assess any extension into the orbit or intracranial compartment, but, unfortunately it can’t study bone detail.

Its indications are in complement of the CT scan in case of diagnosis doubt in CT scan between mucocele and other tumors or inflammatory lesions, in case of sphenoid location and in endocranial or orbital extension.

The MRI appearance of paranasal sinus mucoceles is quite variable, depending on the composition of the mucocele. The usual signal characteristics are a low intense T1 and a high intense T2 but any combination of signal intensity may be seen depending on the presence of blood products or the degree of hydration of the contents. The appearance consisted of hyperintense signal on both T1 and T2 type images, corresponding to more hydrated secretions, which are also high in protein content.

We have noted variable presentation of mucocele in MRI from hypo to hyperintensity T1 and T2 but in all cases, we have noted no enhancement after injection of gadolinium.

CONCLUSION

The presentations of mucoceles on imaging are quite variable depending on its contents. Practicians should know the typical as well as atypical findings. Special care should be taken with regard to differential diagnosis and associated cases.
