ABSTRACT

Pleomorphic adenomas are the most common benign parotid tumours in all populations. Management always consists of a curative superficial parotidectomy. However, rare cases described, in which these histological benign tumors metastasize to distant sites. We present an example of a recurrent parotid pleomorphic adenoma with a contralateral supraclavicular lymph node metastasis after several surgical interventions.

Case report
In this case, we reported a case of a 29-years male with extensive metastasis in submandibular, submental and also very rarely seen contralateral supraclavicular lymph node metastasis. Parotidectomy with preservation of facial nerve and radiotherapy was given to the patient since the lesions were very aggressive.

Conclusion
The patient had several surgical interventions, so it is essential to do meticulous resection in the first surgery to prevent local recurrence and distant metastasis.

Keywords
Pleomorphic adenoma; Metastasizing pleomorphic adenoma; Salivary gland benign neoplasia.

INTRODUCTION

Pleomorphic adenoma is a benign tumour that has elements of both epithelial and mesenchymal tissues. Pleomorphic adenoma is a tumour of variable capsulation characterized microscopically by architectural rather than cellular pleomorphism, most commonly with a tissue of mucoid, myxoid or chondroid appearance which consists of the salivary glands.

It consists of approximately 3% of all head and neck tumours and about 70-80% of these neoplasms occur in the major salivary glands. The tumour most commonly found in the parotid or submandibular glands. Incidence of pleomorphic adenoma varies from 2 to 3.5% with a female preponderance, 3rd and 6th decades are peak ages for pleomorphic adenoma. Neck irradiation is a very strong predisposing factor while the link between the development of pleomorphic adenoma and a simian virus is not clear yet.

Although pleomorphic adenoma is a benign tumour sometimes it shows recurrence and also transformation to malign tumour with an incidence of 2 to 7%. This makes pleomorphic adenomas challenging to manage compared to other salivary gland tumours. On the other hand, pleomorphic adenoma shows malignant behavior with benign histology. This is a very rare entity and its incidence is not clear. There are no studies done on this form of pleomorphic except case reports.
In this article, we present a very unique case of metastasizing pleomorphic adenoma having contralateral supraclavicular non symptomatic metastatic lesions. This will be first case in the literature with contralateral supraclavicular metastasis.

CASE REPORT

A 29-years-old male patient with complaints of a mass in left submandibular gland was referred to our hospital. The patient was not having any other significant complaints.

Clinical examination exhibited a relatively mobile, soft mass located in the left submandibular and submental neck region. Magnetic resonance imaging (MRI) revealed extensive left submandibular and submental subcutaneous mobile conglomerate lesions but what was unique for this case was a single lesion on the right supraclavicular region similar to the main lesion found incidentally on MRI (Figures 1A and 1B).

The patient was operated in another hospital in 2003 and his first pathologic report after the surgery showed pleomorphic adenoma, unfortunately, surgical margins were very near to a tumour. After an extended period of irregular follow-up in 2013, the patient came up with painless swelling on the left neck just next to the scar of the previous incision. Fine needle aspiration resulted showed a pleomorphic adenoma and local excision was performed. The patient discontinued the follow-up until 2017. He applied to our clinic with extensive submental and submandibular round and soft subcutaneous masses (Figures 2A and 2B). All other otorhinolaryngology examination and systematic examination was regular.

Originally tumour was in the submandibular gland but in the last recurrence, the tumour was extending to the inferior part of the parotid gland. The patient underwent total parotidectomy with facial nerve preservation and ipsilateral neck dissection.

Pathologic examination revealed a timorous lesion in a transparent, nodular structure with a white color in different sizes, holding the entire cross-sectional surface in sections of the left parotid and neck dissection with a size of 15.5×5.5×3.5 cm with an ellipsoid skin of 7.5×1.3 cm in size, macroscopically.

On the other hand, there were some white-colored pieces in the right supraclavicular region with 3×3×1 cm size, transparent material with nodular structure and some fat tissue.

Microscopic examination of the left parotid and neck dissection showed that the chondromyxoid stroma composed of fibroblasts and epithelioid types of cells in some areas of the abortive ducts. Also in some areas, there were a more solid cellular atyp...
and no mitotic tumour proliferation. In the histopathological examination of the material from the right supraclavicular region, there was nodular tumour proliferation with similar microscopic features observed in the fatty tissue of the expansive parent material (Figures 3A, 3B and 3C).

In the immunohistochemical study performed, GFAP focal positivity, BCL2 focal positivity and S100 positivity were found. Ki 67 proliferation index was 1%. Histopathologically, there was no evidence of malignancy in both materials, and the findings were consistent with benign pleomorphic adenoma.

DISCUSSION

Pleomorphic adenoma is a benign tumour that has elements of both epithelial and mesenchymal tissues. Pleomorphic adenomas tend to transform to malignancy. Also in very rare cases, pleomorphic adenomas show clinically malignant behaviour while histologically remaining benign. This kind of tumours is called metastasizing pleomorphic adenoma (MPA).1,4

World Health Organization (WHO) classifies neoplasms that show malignant transformation as malignant epithelial tumours.5 However, controversy still exists on rare occasions in which metastasis occurs without malignant transformation. Previously it was considered as benign neoplasia; however, the WHO new classification on head and neck tumours found as a malignant.1 The high mortality rate of around 50% makes them considered as malignant tumours.

The exact incidence of metastising pleomorphic adenomas is not known. However, many cases of metastasizing pleomorphic adenoma have been reported since the early 1940s. McGarry et al6 analysed 52 cases, while Knight et al6 performed a systemic review of case reports from 1942 to 2014 and found 80 cases. LiVolsi and Perzin reviewed 47 cases of metastasizing pleomorphic adenoma.7 Sites of metastasis were bone 36.6%, lung 33.8% and cervical lymph nodes 20.1%.

There are several hypotheses about the mechanism of metastasis of pleomorphic adenomas: which are incomplete enucleation, direct seeding, hematogenic and lymphatic routes. Nourai et al8 reported a series of 42 cases with (MPA), that incomplete excision of the primary pleomorphic adenoma was the most influential factor associated with local recurrence and distant metastasis. In this case, two previous surgical interventions were performed, and the surgical margins of the first surgery were very close to the tumour. Having previous operations supports the hypothesis that inadequate surgical excision is the primary cause of recurrence in this case. But single contra-lateral supraclavicular metastasis shows that incomplete surgery is not the only reason for metastasis.

Chen et al9 reported 20 of 24 tumours metastases hematogenously, whereas 4 of 24 spread via the lymphatic route, while Wenig et al10 also reported that 8 of 11 tumours metastasizing hematogenously and the remaining three spreading via lymphatic channels to nearby cervical and submandibular lymph nodes. Knight et al11 found in their review of 80 cases of metastatic pleomorphic adenoma that 20% of the cases had lymphatic metastasis.

In this case, local metastasis was very extensive, extending to the inferior pole of the left parotid gland. On the other hand, contralateral neck (supraclavicular) lymph node metastasis, which is very far from the original is good evidence for the hypothesis of hematogenic and lymphatic routes of metastasis.

This case is the second case with metastasis to the contra-lateral neck. Miladi et al reported a case of a left submandibular gland pleomorphic adenoma with multiple asymptomatic lymph nodes on both sides of the neck.11 All reported cases had ipsilateral lymph node metastasis, metastases to the contra-lateral supraclavicular region and latency period between recurrence and metastasis gives strong evidence to consider metastasizing pleomorphic ade-
Pleomorphic adenoma with lung metastases composed exclusively of benign elements, showing histological evidence for the link between metastatic pleomorphic adenoma and carcinoma ex-pleomorphic adenoma. Although there is no clear evidence for the role of radiation and chemotherapy in the treatment and prevention of metastasis. But in Liu et al., reported in a retrospective study of 128 patients, 55 patients received radiotherapy, and the primary reason for radiation was recurrence after surgery. They also presented that they achieved local control in 13 of 16 patients (82%) at ten years with a median dose of 45 Gy. While local control with surgery alone achieved in 1 out of 17 patients. Chen et al. and Wallace et al. reported local control of 94% and 75% respectively, with combined surgery and radiotherapy. In this case with a multi-disciplined approach, the patient had radiotherapy and no recurrence seen until in our regular follow-ups.

CONCLUSION

As reported in the literature, the first surgery is critical, especially in young female patients. It’s strongly recommended to do apparent surgery and avoid capsular rupture. So it’s also essential to investigate for metastasis and treat them as a low-grade malignant tumour.
