ABSTRACT

Aim
The objectives of this study were to assess the prevalence of major gastrointestinal tract (GIT) parasite of cattle’s and associated major risk factor at Jimma municipal abattoir.

Method
A cross-sectional study with a simple random sampling method was conducted from November, 2018 to April, 2019.

Result
Based on the carpological examination, from 400 animals that were presented for slaughter at Jimma municipal abattoir, 46.8% (187) of animals have at least one GIT parasite. The study detected five genera of GIT parasite which were Strongyle-type, Trichuris spp., Monezia spp., Paramphistomum spp. and Eimeria spp. with prevalence of 28.9% (54), 4.8% (9), 3.2% (6), 38.5% (72) and 13.4% (25), respectively while mixed parasites has 11.2% (21) of prevalence. The diversity of those mixed parasite were Strongyle type with Paramphistomum spp., Paramphistomum spp. with Eimeria spp., Eimeria spp. with Trichuris spp., Strongyle spp. with Monezia spp., Paramphistomum spp with Monezia spp,, Strongyle type with Eimeria spp. and Paramphistomum spp with Trichuris spp. with the prevalence of 42.9%, 14.3%, 14.3%, 9.5%, 14.3%, 23.8% and 10.0% respectively. The prevalence of gastrointestinal parasite based on origin of the study animals was recorded and showed statistically significant difference with p-value of 0.001 (p≤0.05) and the prevalence was highest in Seka Chekorsa and followed by Kersa, Mena, Oma Nada and Dedo in decreasing order. The risk factor related to the age showed statistically significant difference (p<0.05) in which GIT parasite has highest prevalence in young and least in old and moderate in adult cattle. This study showed that infection prevalence was highest in animal with poor body condition followed by medium and good body condition scores and difference was statistically significant (p<0.05). In addition, the difference between the season also recorded and found statistically significant (p<0.05).

Conclusion
The finding showed that good management and strategic anthelmintic treatment need to be applied in the area to reduce the prevalence of the GIT parasites of cattle and their risk factor to lessen economic loss caused by the parasite.

INTRODUCTION

Livestock systems occupy about 30 per cent of the planet's ice-free terrestrial surface area and are a significant global asset with a value of at least $1.4 trillion. They are important source of animal protein in many countries of the world, supplying a good percentage of the daily meat and dairy products in cities and villages, flexible income for family units, employment, farm energy and manure. It is increasingly organized in long market chains that employ at least 1.3 billion people globally and directly support the livelihoods of 600 million poor smallholder farmers in the developing world. According to Herrero et al, the total demand for livestock products might almost double by 2050, mostly in the developing world owing to increases in population density, urbanization and increased incomes.

Ethiopia is one of the African country that possess about 59.5 million cattle, 30.7 million sheep, 30.2 million goats and 59.5 million chickens. They contribute about 16.5% of the national gross domestic product (GDP) and 35.6% of the agricultural GDP. In spite of the large population of cattle, productivity in Ethiopia is low due to poor nutrition, reproduction insufficiency, management constraints and prevailing animal disease. Gastrointestinal parasites are considered as the major diseases of cattle in the country. It is one of the major causes of wastage and decreased productivity exerting their effect through mortality, morbidity, decreased growth rate, weight loss in young growing calves and late maturity of slaughter stock, reduced milk and meat production and working capacity of the animal mainly in developing countries.

The numbers of gastrointestinal tract (GIT) parasite species are known to infect cattle worldwide. The most important ones include nematodes like Strongyle species (Haemonchus, Ostertagia, Trichostrongylus, Cooperia) and trematodes of economic importance Fasciola species (Fasciola hepatica and Fasciola gigantica) and Paramphistomum species (Paramphistomum cervi), while cestodes like Monezia species (Monezia benedeni and Monezia expansa) could also be important constraints in animal production. There are many associated risk factors influencing the prevalence and severity of GI helminths. These include age, sex, and weather condition and husbandry or management practices.

Many cross-sectional study on GIT parasite of cattle were carried out in many part of Ethiopia. According to Etschewot, the study conducted in and around Holleta indicated that the overall prevalence parasitic infection of cattle was 82.8%. The predominant helminths egg identified were trematodes (Fasciola and Paramphistomum spp.) 80.6%, Strongyles 66.25%, mixed infection (Trematodes and Strongyles) 63.12%, while others such as Trichuris and Monezia 1.5%. Other study conducted on gastrointestinal (GI) parasite of ruminants in Western Oromia also showed that the overall prevalence of GIT parasites was 69.6% in cattle with predominant prevalence of Strangles and Eimeria parasite. In addition according to Tulu et al the study on major gastro-intestinal helminths parasites of cattle in Tulo District, West Hararghe Zone shows that 50.08% was recorded with one or more species of GI helminth parasites.

Furthermore, the abattoirs are instruments for the insurance of wholesome meat and meat products as well as providing abattoir by-products for livestock base industries. More importantly, abattoirs are used for the purpose of surveillance against animal and zoonotic diseases. The importance of abattoir records in analysis of prevalence rate and planning strategy for the control of livestock diseases cannot be undermined. However, there was no enough study that was carried out on GIT parasite of cattle that slaughtered at different municipalities’ of abattoirs of Ethiopia including Jimma municipal abattoir yet. Therefore, the objectives of this study were to assess the prevalence of GIT parasites of cattle come for slaughter and associated major risk factor at Jimma municipal abattoir. This is with a view of providing a baseline epidemiological data on this group of parasites and other livestock diseases of economic and zoonotic importance in an ongoing study in Ethiopia.

MATERIALS AND METHODS

Study Area Description

The study was carried out on the cattle that were come for slaughter at Jimma municipal abattoir from November 2018 to April 2019. Jimma is the largest city in south-western Ethiopia. It is a special zone of the Oromia Region about 352 km southwest of Addis Ababa. It has latitude of 7013’ to 8056’ N and longitude of 35052’ to 37037’ E, and an elevation ranging from 880 to 3360 m above sea level. The area receives a mean annual rainfall of about 1,530 mm, which comes from long and short rainy seasons. The average minimum and maximum annual temperature ranges between 14.4 and 26.7 °C, respectively. The predominant economic activities involve mixed farming, which broadly includes cultivation of cereal crops, cash crops including primarily coffee and production of livestock. The total livestock population of Jimma zone is estimated to constitute, 2.02 million cattle, 288,411 goats, 942,908 sheep, 152,434 equines, 1,139,735 poultry and 418,831 bee hives.

Study Population

All cattle that were presented for slaughter at Jimma municipal abattoir during the study periods were considered as study animals for the presence of gastrointestinal parasite. Those animals were transported to the abattoir from different district of Jimma zone and all of them were zebu cattle. Sex of examined animals was male. Female animals were not slaughtered in abattoir during this study.

Study Design

A cross-sectional study was conducted to determine the prevalence of GIT parasite of cattle which were presented for slaughter at Jimma abattoir and to investigate the major risk factors influencing the prevalence of parasite infection in cattle.
Sampling Methods and Sample Size

The sampling method that was used in this study was random sampling method. Animals were selected in the lottery method of simple random sampling in which all the ID of the cattle that were transported to Jimma municipal abattoirs written on separate slips of paper of the same size, shape and colour and they were folded and mixed up in a container. The required numbers of slips were selected at random for the desire sample.

The sample size was determined by the formula stated in Thrustfiled with 95% confidence interval and 5% of absolute precision and considering that expected prevalence is 50% used since there is no reported studies at Jimma municipal abattoir. Hence, the sample size was calculated to be 384.

\[
N = \frac{(1.96)^2 \cdot P_{exp} \cdot (1 - P_{exp})}{d^2}
\]

Where, \(N\) = required sample size, \(P_{exp}\) = Expected prevalence (50%), \(d\) = desired absolute precision (0.05). Accordingly, 384 samples were needed, however, 400 cattle was sampled and examined to increase precise of the mean. It was increased by 4%.

Data and Sample Collection

Fecal samples was collected directly from rectum of animals in clean universal bottle then labeled and kept in icebox and immediately transported to parasitology laboratory of Jimma University College of Agriculture and Veterinary Medicine and was examined. Those that were not examined on that time were stored in refrigerator at 4 °C and examined in the following day. During sample collection various potential risk factors including sex, age, breed, and body condition score were recorded. The age of cattle was determined by dentition using the given standard. Cattle were categorized as young, those in range of 5 to 10-years were grouped into three age categories; under 5-years of age, they were categorized as adult and those above 10-years were classified as old. In addition to that body conditions of animals were recorded based on the scoring system described by Nicholson et al. The information and data that were collected on GI parasite of cattle and its risk factors during the period were recorded in excel sheet and analyzed using SPSS version 20. Descriptive Statistics was used determine the prevalence through percentage and frequency. The significance of association between and among the considered variables was determined using \(p\)-value, chi-square (\(\chi^2\)) test statistics. Association between variables was said to exist if the calculated level of significance is less than 5% (\(p<0.05\)) at 95% confidence level.

RESULTS

Overall Prevalence of GIT Parasite

Based on the carpological examination, from 400 fecal samples of animals that were come to Jimma municipal abattoir for slaughter, 46.8% (187) of animals had GIT parasite. Variation had been observed on the prevalence of different types of gastrointestinal nematode parasites. 166 (88%) of the animals were positive with single parasite whereas 21 (11.2%) of the animals were positive for mixed types of GIT parasite. The study was detecting five genera of GIT parasite. Those were Strongyle type egg, Trichuris spp., Monezia spp., Paramphistomum spp. and Eimeria spp. with the prevalence of 28.9% (54), 4.8% (9), 3.2% (6), 38.5% (72) and 13.4% (25), respectively. The diversity of those mixed parasite were Strongyle type with Paramphistomum spp., Paramphistomum spp. with Eimeria spp., Eimeria spp. with Trichuris spp., Strongyle type with Monezia spp., Paramphistomum spp. with Monezia spp., Strongyle type with Eimeria spp. and Paramphistomum spp. with Trichuris spp. and their prevalence were 42.9%, 14.3% , 14.3%, 9.5%, 14.3%, 23.8% and 10.0% , respectively (Tables 1 and 2).

Prevalence of Gastrointestinal Parasite Based on the Risk Factor

The prevalence of gastrointestinal parasite based on origin of the study animals was identified and out of the total 75 animals from Kersa, 87 from Dedo, 95 from Seka Chekorsa, 89 from Oma Nada, and 54 from Mena, 50.7% (38), 34.5% (30), 65.3% (62), 36.0% (32), and 46.3% (25), respectively of them were positive at least for one GIT parasite. The difference was statistically significant with \( p \)-value of 0.001 \((p \leq 0.05)\) and Chi-square value of 22.971. Young, adult and old animals were found to be infested with a prevalence of 75.4%, 75.4% and 19.1, respectively with statistically significant difference with \( p \)-value of 0.001 \((p < 0.05)\) and \( \chi^2 \) of 77.591. Infec-
tion prevalence was significantly highest in animal with poor body condi-
tion followed by medium and good body condition scores and difference was statistically significant with \( p \)-value was 0.001 \((p < 0.05)\) and \( \chi^2 \) of 34.411. The overall infection prevalence ac-
cording to body condition grades, 63.2%, 49.5% and 24.0%, respectively (Table 3).

In addition, the prevalence of GIT parasite of cattle in the different month was recorded and the associations found statistically significant \((p \leq 0.05)\) and its \( p \)-value was 0.001. The preva-
nce was 65.0%, 48.8%, 37.5%, 43.8% and 38.8% in November, December, January, February and March, respectively.

**DISCUSSION**

Gastrointestinal tract parasites cause severe infection to domestic animals worldwide. Those GIT parasite mostly caused by nema-
tode, cestode, trematode and protozoa in domestic animals and af-
facts fertility, work capacity, involuntary culling, reduction in food intake, weight & milk production and higher mortality rate.\(^{18,19}\)

The findings of present study show that from 400 of the cattle screened, 46.8% (187) of animals had at least one GIT para-
site infection which was similar with the result study of Adedipe et al\(^{20}\) on the prevalence gastrointestinal helminths in slaughtered cattle in Ibadan, South-Western Nigeria which was 41.6% and of Lemy and Egwunyenga\(^{21}\) on the prevalence of parasitic helmin-
thes at various abattoirs in Abraka, Delta State, Nigeria which was
50.4%. However, it was less than that of other study result of Wa-
ruiru et al\(^{22}\) in the central Highlands of Kenya, of Elele et al\(^{23}\) at selected abattoirs in Port Harcourt, South-south, Nigeria, of Usman et al\(^{24}\) in Katagum Abattoir Of Bauchi State, Nigeria, of Okike et al\(^{25}\) at Aba, Nigeria, of Luka et al\(^{26}\) at Gombe Abattoir, Gombe State, North-Eastern Nigeria and of Bisimwa et al\(^{12}\) which were
86.8%, 62.1%, 61.8%, 87.41%, 80.72% and 74%, respectively. In addition to that the result of the study was greater than other study results which were conducted in Wukari Local Government abat-
toir, in Taraba State, North-Eastern Nigeria\(^{20}\) and in Wudil Local Government Area abattoir in Kano State, Nigeria\(^{27}\) with the same overall prevalence of 34.9%. These differences could be due to the periods or seasons in which the studies were conducted, the management system, topography climatic condition that favors the survival of infective stage of the parasite and intermediate hosts as well as the sources of cattle sampled in the various regions.

In this study different genus of parasite was found. Five genera of parasite was observed. Those are Strongyle type, Trichu-
ris spp., Paramphistomum spp., Eimeria spp. and Monezia spp. Those GIT were encountered in the study had been reported by other

researchers in different parts of the other country.12,20-26

Furthermore, the study showed a statistically significant difference among the age of animals as risk factor for GIT parasite also found in this study. Young animals were most infected when compared with adult and old animals with prevalence of 75.4%, 35.3% and 19.1%, respectively. There was a decrease in infection rate (prevalence) as age increased. This may be due to the result of acquired immunity (natural) with age which is manifested by humoral immune response through frequent challenges and expel the ingested parasite before they establish infection. The natural immunity of the animals influenced by nutrition and general condition of the animal.28 The result was similar with the study result of Shitta et al35 in which young has prevalence of 45.30% than the adult examined which had 30.10%.

In addition the study shows that there was statistically significant difference of GIT parasite prevalence in different months in which sample was collected. The highest prevalence of helminths parasitic infections (65.0%) was recorded in November which was included in the rainy season and lowest prevalence (37.5%) was recorded in January which was categorized in dry season. This finding was in agreement with Wadhwa et al36 and Kumar et al19 who recorded higher incidence of parasitic infection during rainy season and lower prevalence during dry season. This may be due to high-moisture content and temperature which favours the growth and development of larvae on pasture resulting in increased contact between the host and parasites. In addition to that the reason of the lowest prevalence (37.5%) was recorded in January might be the January was come followed driest month of the December (en.climate-data.org). Thus, there were no available larvae of parasite whose cycle depends on optimum temperature and moisture that were infecting the cattle.

CONCLUSION AND RECOMMENDATIONS

Generally, gastrointestinal parasites are considered as the major diseases of cattle which are one of the major causes of wastage and decreased productivity exerting their effect through mortality, morbidity, decreased growth rate, weight loss in young growing calves and late maturity of slaughter stock, reduced milk and meat production and working capacity of the animal mainly in developing countries. The study was performed to identify and find the prevalence of GIT parasite at abattoir. Five types of GIT parasites were identified including Strongyle type, Trichuris spp., Paramphistomum spp., Eimeria spp. and Monezia spp. In addition this study identified the potential risk factors such as age, body condition and the origin of the animals and season of the year which showed statistically significant difference associated with high-prevalence rate. Therefore based on the above conclusion the following recommendations are forwarded:

• Animals should be management in good manner to lessen their susceptibility
• periodical deworming need to be applied in the area to reduce the prevalence of the GIT parasites of cattle
• The habitat of the intermediate host should be the destructed if it is possible

ACKNOWLEDGEMENTS

First and above all I would like to give my faith full thanks from my deep heart to my heavenly father, the almighty God and my lord Jesus Christ for all things. In addition to that my deepest gratitude extends to my family for their encouragement, support, advice and moral appreciation.

Collection of Fecal Samples and Laboratory Procedures

Collection of fecal samples: Collection of faecal samples is performed according to the following procedure;

- Faecal samples for parasitological examination were collected from the rectum of the animal
- Then it was put into universal bottles
- Each universal bottle was clearly labeled with animal identification, date and place of collection.
- Then Samples were packed and dispatched in a cool box to avoid the eggs developing and hatching.
- As soon after passage from the animal as possible examination was carried out.
- But when the processing of a fecal specimen delayed for some reason, it was preserved for the followed day be used; it was fixed with 10% formalin. Fixative added to feces at a ratio 3:1 (v:v) and mixed well.

Processing fecal samples

Floatation method

Principle: The simple test tube flotation method is a qualitative test for the detection of nematode and cestode eggs and coccidiaoocysts in the faeces. It is based on the separating of eggs from faecal material and concentrating them by means of a flotation fluid with an appropriate specific gravity.

Application: This is a good technique to use in initial surveys to establish which groups of parasites are present.

Equipment

- Beakers or plastic containers
- A tea strainer (preferably nylon) or double layer cheesecloth
- Measuring cylinder or other container graded by volume
- Fork, tongue blades or other type of stirring rod
- Test tube
- Test tube rack or a stand
- Microscope
- Microslides, coverslips
- Balance or teaspoon
- Flotation fluid

Procedure

a. Put approximately 3 g of faeces (weigh or measure with a precalibrated teaspoon) into Container 1.
b. Pour 40 ml flotation fluid into Container 1.
c. Mix (stir) faeces and flotation fluid thoroughly with a stirring device (tongue blade, fork).
d. Pour the resulting faecal suspension through a tea strainer or a double-layer of cheesecloth into Container 2.
e. Pour the faecal suspension into a test tube from Container 2.
f. Place the test tube in a test tube rack or stand.
g. Gently top up the test tube with the suspension, leaving a convex meniscus at the top of the tube and carefully place a coverslip on top of the test tube.
h. Let the test tube stand for 16 minutes.
i. Carefully lift off the coverslip from the tube, together with the drop of fluid adhering to it, and immediately place the coverslip on a microscope slide (Table 1.1).

Sedimentation technique (for trematode eggs)

Principle: The sedimentation technique is a qualitative method for detecting trematode eggs (Paramphistomum) in the faeces. Most trematode eggs are relatively large and heavy compared to nematode eggs. This technique concentrates them in sediment.

Application: This is a procedure to assess the presence of trematode infections. It is generally run only when such infections are suspected (from previous postmortem findings on other animals in the herd/flock area), and is not run routinely. The procedure can be used to detect liver fluke (Fasciola) and Paramphistomum eggs.

Equipment

- Beakers or plastic containers
- A tea strainer or cheesecloth
- Measuring cylinder
- Stirring device (fork, tongue blade)
- Test tubes
- Test tube rack
- Methylene blue
- Microslide, coverslips
- Balance or teaspoon
- Microscope

Procedure

a. Weigh or measure approximately 3 g of faeces into Container 1.
b. Pour 40 ml of tap water into Container 1.
c. Mix (stir) thoroughly with a stirring device (fork, tongue blade).
d. Filter the faecal suspension through a tea strainer or double-
layer of cheesecloth into Container 2.
e. Pour the filtered material into a test tube.
f. Allow to sediment for 5 minutes.
g. Remove (pipette, decant) the supernatant very carefully.
h. Resuspend the sediment in 5 ml of water.
i. Allow to sediment for 5 minutes.
j. Discard (pipette, decant) the supernatant very carefully.
k. Stain the sediment by adding one drop of methylene blue.
l. Transfer the sediment to a microslide. Cover with a coverslip.

Microscopically examination of prepared samples: the prepared samples on microslides from the simple test tube flotation method, the simple flotation method and the sedimentation method are examined under a microscope at the magnifications listed in Table 1.2
